(Received May 13, 2012)

Abstract

The aim of this paper is to study the high order difference scheme for the solution of a fractional partial differential equation (PDE) in the electroanalytical chemistry. The space fractional derivative is described in the Riemann-Liouville sense. In the proposed scheme we discretize the space derivative with a fourth-order compact scheme and use the Grunwald-Letnikov discretization of the Riemann-Liouville derivative to obtain a fully discrete implicit scheme and analyze the solvability, stability and convergence of proposed scheme using the Fourier method. The convergence order of method is $O(\tau + h^4)$. Numerical examples demonstrate the theoretical results and high accuracy of proposed scheme.

Keywords: Electroanalytical chemistry, reaction-sub-diffusion, compact finite difference, Fourier analysis, solvability, unconditional stability, convergence.

1. Introduction

In recent years there has been a growing interest in the field of fractional calculus [6, 16, 22, 26]. Fractional differential equations have attracted increasing attention because they have applications in various fields of science and engineering [4]. Many phenomena in fluid mechanics, viscoelasticity, chemistry, physics, finance and other sciences can be described very successfully by models using mathematical tools from fractional calculus, i.e., the theory of derivatives and integrals of fractional order. Some of the most applications are given in the book of Oldham and Spanier [19] and the papers of Metzler and Klafter [15], Bagley and Trovik [1]. Many considerable works on the theoretical

1 Corresponding author: Email: a._mohebbi@kashanu.ac.ir
analysis [5, 25] have been carried on, but analytic solutions of most fractional differential equations cannot be obtained explicitly. So many authors have resorted to numerical solution strategies based on convergence and stability analysis[4, 10, 13, 24]. Liu has carried on so many work on the finite difference method of fractional differential equations [14, 11, 12]. There are several definitions of a fractional derivative of order $\alpha > 0$ [22, 19]. The two most commonly used are the Riemann-Liouville and Caputo. The difference between two definitions is in the order of evaluation [18]. We start with recalling the essentials of the fractional calculus. The fractional calculus is a name for the theory of integrals and derivatives of arbitrary order, which unifies and generalizes the notions of integer-order differentiation and n-fold integration. We give some basic definitions and properties of the fractional calculus theory.

**Definition 1.** For $\mu \in \mathbb{N}$ and $x > 0$, a real function $f(x)$, is said to be in the space $C_\mu$ if there exists a real number $p > \mu$ such that $f(x) = x^p f_1(x)$, where $f_1(x) \in C(0, \infty)$, and for $m \in \mathbb{N}$ it is said to be in the space $C^m_\mu$ if $f^m \in C_\mu$.

**Definition 2.** The Riemann-Liouville fractional integral operator of order $\alpha > 0$ for a function $f(x) \in C_\mu$, $\mu \geq -1$ is defined as

$$J^\alpha f(x) = \frac{1}{\Gamma(\alpha)} \int_0^x (x-t)^{\alpha-1} f(t) dt, \quad \alpha > 0, \; x > 0, \; J^0 f(x) = f(x).$$

Also we have the following properties

- $J^\alpha J^\beta f(x) = J^ {\alpha+\beta} f(x)$,
- $J^\alpha J^\beta f(x) = J^\beta J^\alpha f(x)$,
- $J^\alpha x^\gamma = \frac{\Gamma(\alpha+1)}{\Gamma(\alpha+\gamma+1)} x^{\alpha+\gamma}$.

**Definition 3.** If $m$ be the smallest integer that exceeds $\alpha$, the Caputo Riemann-Liouville fractional derivatives operator of order $\alpha > 1$ is defined as, respectively,

$$C_0^D_t^\alpha f(x) = \begin{cases} \frac{1}{\Gamma(m-\alpha)} \int_0^x (x-t)^{m-\alpha-1} \frac{d^m f(x)}{dx^m} \bigg|_{x=t} dt, & m-1 < \alpha < m, \; m \in \mathbb{N} \\ \frac{d^m f(x)}{dx^m}, & m = \alpha, \end{cases} \tag{1.1}$$
Numerical solution of a fractional PDE in the electroanalytical chemistry

Due mainly to the works of Oldham and his co-authors [7, 8, 9, 20, 21], electrochemistry is one of those fields in which fractional-order integrals and derivatives have a strong position and bring practical results. Although the idea of using a half-order fractional integral of current, $\int_0^{\infty} i(t) dt$, can be found also in the works of other authors, it was the paper by Oldham [20] which definitely opened a new direction in the methods of electrochemistry called semi-integral electroanalysis. One of the important subjects for study in electrochemistry is the determination of the concentration of electroactive species near the electrode surface. The method suggested by Oldham and Spanier [21] allows, under certain conditions, replacement of a problem for the diffusion equation by a relationship on the boundary (electrode surface). Based on this idea, Oldham [20] suggested the utilization in experiment the characteristic described by the function

$$ m(t) = 0 D_t^{-1/2} i(t) $$

which is the fractional integral of the current $i(t)$, as the observed function, whose values can be obtained by measurements. Then the subject of main interest, the surface concentration $C_s(t)$ of the electroactive species, can be evaluated as

$$ C_s(t) = C_0 - k_0 D_t^{-2} i(t), $$

where $k$ is a certain constant described below, and $C_0$ is the uniform concentration of the electroactive species throughout the electrolytic medium at the initial equilibrium situation characterized by a constant potential, at which no electrochemical reaction of the considered species is possible. The relationship (1.3) was obtained by considering the following problem for a classical diffusion equation [9]

$$ \frac{\partial C(x,t)}{\partial t} = D_s \left[ \frac{\partial^2 C(x,t)}{\partial x^2} \right], \quad 0 < x < \infty, \quad t > 0, $$

$$ C(\infty, 0) = C_0, \quad C(x, 0) = C_0, $$

$$ D_s \left[ \frac{\partial C(x,t)}{\partial t} \right]_{t=0} = \frac{i(t)}{nAF}.$$
Where $D_*$ is diffusion coefficient. $A$ is the electrode area, $F$ is Faraday’s constant and $n$ is the number of electrons involved in the reaction, the constant $k$ in (1.3) is expressed as

$$k = \frac{1}{nAF\sqrt{D_*}}.$$ 

Instead of the classical diffusion equation (1.4), it is possible to consider the fractional order diffusion equation [23]

$$\frac{\partial C(x,t)}{\partial t} = 0 D_t^{1-\gamma} \left[ \frac{\partial^2 C(x,t)}{\partial x^2} \right],$$

(1.5)

where $0 < \gamma < 1$. In this paper, we consider the generalized form of the Eq. (1.5) with the nonlinear source term and on a bounded domain with the following form

$$\frac{\partial u(x,t)}{\partial t} = 0 D_t^{1-\gamma} \left[ \kappa_1 \frac{\partial^2 u(x,t)}{\partial x^2} - \kappa_2 u(x,t) \right] + f(u(x,t), x, t),$$

(1.6)

$$0 \leq x \leq L, \quad 0 \leq t \leq T,$$

The boundary and initial conditions are

$$u(0, t) = \varphi_1(t), \quad u(L, t) = \varphi_2(t), \quad 0 < t < T,$$

(1.7)

$$u(x, 0) = \psi(x), \quad 0 < x < L.$$ 

(1.8)

where $0 < \gamma \leq 1$, $\kappa_1 > 0$, $\kappa_2 \geq 0$ and the source term $f(u, x, t) \in C^1[0, L]$. The symbol $0 D_t^{1-\gamma}$ is the Riemann-Liouville fractional derivative operator and is defined as

$$0 D_t^{1-\gamma} u(x, t) = \frac{1}{\Gamma(\gamma)} \frac{\partial}{\partial t} \int_0^t (t - \eta)^{1-\gamma} \frac{\partial}{\partial \eta} u(x, \eta) d\eta.$$ 

Where $\Gamma(\cdot)$ is the gamma function. Also, let $f(u, x, t)$ satisfies the Lipschitz condition with respect to $u$:

$$|f(\bar{u}, x, t) - f(\tilde{u}, x, t)| \leq \ell |\bar{u} - \tilde{u}|, \quad \forall \bar{u}, \tilde{u}$$

where $\ell$ is the Lipschitz constant. The aim of this paper is to propose a numerical scheme of order $O(\tau + h^4)$ for the solution of Eq. (1.6). We apply a fourth order difference scheme for discretizing the spatial derivative and Grunwald-Letnikov discretization for the Riemann-Liouville fractional derivative. We will discuss the stability of proposed method is a by the Fourier method and show that the compact finite difference scheme converges.
with the spatial accuracy of fourth order using matrix analysis. The outline of this paper is as follows. In Section 2, we introduce the derivation of new method for the solution of Eq. (1.6). This scheme is based on approximating the time derivative of mentioned equation by a scheme of order $O(\tau)$ and spatial derivative with a fourth order compact finite difference scheme. In this section we obtain the matrix form of the proposed method and show the solvability of it. In Section 3 we prove the unconditional stability property of method. In Section 4 we present the convergence of method and show that the convergence order is $O(\tau + h^4)$. In Section 5 we report the numerical experiments of solving Eq. (1.1) with the method developed in this paper for several test problems. Finally concluding remarks are drawn in Section 6.

2. Derivation of Method

For positive integer numbers $M$ and $N$, let $h=L/M$ denotes the step size of spatial variable, $x$, and $\tau=T/N$ denotes the step size of time variable, $t$. So we define

$$x_j = jh, \quad j = 0, 1, 2, ..., M,$$

$$t_k = k \tau, \quad k = 0, 1, 2, ..., N.$$  

The exact and approximate solutions at the point $(x_j, t_k)$ are denoted by $u_j^k$ and $U_j^k$ respectively. We first state the fourth-order compact scheme of second derivative in the following lemma.

Lemma 1([4]). The fourth-order compact difference operator with maintaining three point stencil to approximate the $u_{xx}$ is

$$\frac{\delta^2 u_j^k}{h^2 \left(1 + \frac{1}{12} \delta^2 \right)} = \frac{\partial^2 u_j^k}{\partial x^2} - \frac{1}{240} \frac{\partial^4 u_j^k}{\partial x^4} h^4 + O(h^6), \quad (2.1)$$

in which $\delta^2 u_j = (u_{j+1} - 2u_j + u_{j-1})$.

Now using the relationship between the Grunwold-Letnikov formula and the Riemann-Liouville fractional derivative, we can write
\[ oD_t^{1-\gamma} f(t) = \frac{1}{\tau^{1-\gamma}} \sum_{k=0}^{[\frac{t}{\tau}]} \omega_k^{(1-\gamma)} f(t-k\tau) + O(\tau^\nu), \quad (2.2) \]

Where \( \omega_k^{(1-\gamma)} \) are the coefficients of the generating function, that is,

\[ \omega(z, \alpha) = \sum_{k=0}^{\infty} \omega_k^{(\alpha)} z^k \]

We will discuss the case for \( \omega(z, \alpha) = (1-z)^\alpha \) and thus \( p=1 \). In this case the coefficients are \( \omega_0^{(\alpha)} = 1 \) and \( \omega_k^{(\alpha)} = (-1)^k \left( \begin{array}{c} \alpha \\ k \end{array} \right) \frac{\alpha(\alpha-1)\ldots(\alpha-k+1)}{k!} \) for \( k \geq 1 \) and can be evaluated recursively,

\[ \omega_0^{(\alpha)} = 1, \quad \omega_k^{(\alpha)} = \left( \frac{1-\alpha + 1}{k} \right) \omega_k^{(\alpha-1)}, \quad k \geq 1. \quad (2.3) \]

Now, we put

\[ \lambda_l = \omega_l^{(1-\gamma)} = (-1)^l \left( \frac{1-\gamma}{l} \right), \quad l = 0, 1, \ldots, k. \]

So \( \lambda_0 = 1 \). If we consider Eq. (1.6)-(1.8) at the point \( (x_j, t_k) \), we can write

\[ \frac{\partial u(x_j, t_k)}{\partial t} = (0D_t^{1-\gamma}) \left[ \kappa_1 \frac{\partial^2 u(x_j, t_k)}{\partial x^2} - \kappa_2 u(x_j, t_k) \right] + f(u(x_j, t_k), x_j, t_k). \quad (2.4) \]

Since \( f(u, x, t) \) has the first order continuous derivative it follows that

\[ f(u(x_j, t_k), x_j, t_k) = f(u(x_j, t_{k-1}), x_j, t_{k-1}) + O(\tau). \]

Also, we can write

\[ \frac{\partial u(x_j, t_k)}{\partial t} = \frac{u(x_j, t_k) - u(x_j, t_{k-1})}{\tau} + O(\tau), \]

\[ \left( 1 + \frac{1}{12} \delta_s^2 \right) \frac{\partial^2 u(x_j, t_k)}{\partial x^2} = \frac{\delta_s^2 u(x_j, t_k)}{h^2} + O(h^4), \]

\[ oD_t^{1-\gamma} \left( \frac{\partial^2 u(x_j, t_k)}{\partial x^2} \right) = \tau^{a-1} \sum_{i=0}^{k} \lambda_i \frac{\partial^2 u(x_j, t_{k-i})}{\partial x^2} + O(\tau), \]
\[ 0D_t^{1-\gamma}u(x_j,t_k) = \tau^{\alpha-1} \sum_{l=0}^{k} \lambda_l u(x_j,t_{k-1}) + O(\tau), \]

From Eq. (2.4) and above results, we can obtain
\[
\left(1 + \frac{1}{12} \delta_x^2\right)u(x_j,t_{k}) = \left(1 + \frac{1}{12} \delta_x^2\right)u(x_j,t_{k-1}) + \mu_1 \sum_{l=0}^{k} \lambda_l \delta_x^2 u(x_j,t_{k-1}) + \mu_2 \sum_{l=0}^{k} \lambda_l \left(1 + \frac{1}{12} \delta_x^2\right)u(x_j,t_{k-1}) + \tau \left(1 + \frac{1}{12} \delta_x^2\right)f_j^{k-1} + R_j^k
\]

where, \( \mu_1 = \kappa_1 \frac{\tau^2}{h^2}, \) \( \mu_2 = \kappa_2 \tau^2, \) and
\[
R_j^k = O(\tau^2) + O(h^4) \sum_{l=0}^{k} (\kappa_1 \tau^2 \lambda_l).
\]

By omitting the small term \( R_j^k, \) the implicit compact difference scheme for (1.6)-(1.8) is given as follows:
\[
\begin{align*}
\left(1 + \mu_2 + \left(1 + \frac{1}{12} \mu_1 + \frac{\mu_3}{12}\right) \delta_x^2\right)U_j^k &= \left(1 - \lambda_1 \mu_2 + \left(1 + \frac{1}{12} \lambda_1 \mu_2 - \frac{\lambda_1 \mu_2}{12}\right) \delta_x^2\right)U_j^{k-1} + \mu_1 \sum_{l=2}^{k} \lambda_l \delta_x^2 U_j^{k-1} - \mu_2 \sum_{l=2}^{k} \lambda_l \left(1 + \frac{1}{12} \delta_x^2\right)U_j^{k-1} + \tau \left(1 + \frac{1}{12} \delta_x^2\right)f_j^{k-1},
\end{align*}
\]
\begin{align*}
U_j^0 &= \psi(x_j), \quad j = 1, 2, \ldots, M - 1, \\
U_0^k &= \varphi_1(t_k), \quad U_M^k = \varphi_2(t_k), \quad k = 1, 2, \ldots, N.
\end{align*}

Now we denote the solution vector of order \( M - 1 \) at \( t = t_k \) by \( U^k = \mathbf{U}(t_k) = (U_1^k, \ldots, U_M^k)^T. \) We can give the matrix-vector form of (2.7) by
\[ A U^k = \sum_{l=0}^{k-1} B_l U^l + F^k, \quad k = 1, 2, 3, \ldots, N, \quad (2.8) \]

in which

\[ A = \text{tri} \left[ \frac{1}{12} (1 + \mu_2) - \mu_1, \frac{5}{6} (1 + \mu_2) + 2 \mu_1, \frac{1}{12} (1 + \mu_2) - \mu_1 \right], \]

\[ B_I = \lambda_t \text{tri} \left[ \mu_1 - \frac{\mu_2}{12}, -2 \mu_1 - \frac{5}{6} \mu_2, \mu_1 - \frac{\mu_2}{12} \right], \]

\[ B_{k-1} = \text{tri} \left[ \frac{1}{12} (1 - \lambda_t \mu_2), \frac{5}{6} (1 - \lambda_t \mu_2), \frac{1}{12} (1 - \lambda_t \mu_2) \right], \]

\[
F^k = \begin{bmatrix}
-\left( \frac{1}{12} (1 + \mu_2) - \mu_1 \right) U_0^k + \tau \left( 1 + \frac{1}{12} \delta_i^2 \right) f_1^{k-1} + \left( \frac{1}{12} (1 + \lambda_t \mu_2) - \mu_1 \right) U_0^k \\
\tau \left( 1 + \frac{1}{12} \delta_i^2 \right) f_2^{k-1} \\
\vdots \\
\tau \left( 1 + \frac{1}{12} \delta_i^2 \right) f_{M-2}^{k-1} \\
-\left( \frac{1}{12} (1 + \mu_2) - \mu_1 \right) U_M^k + \tau \left( 1 + \frac{1}{12} \delta_i^2 \right) f_{M-1}^{k-1} + \left( \frac{1}{12} (1 + \lambda_t \mu_2) - \mu_1 \right) U_M^k
\end{bmatrix},
\]

where \( \text{tri} [a_1, a_2, a_3]_{(M-1) \times (M-1)} \) denotes a \((M - 1) \times (M - 1)\) tri-diagonal matrix. Each row of this matrix contains the values \( a_1, a_2 \) and \( a_3 \) on its sub-diagonal, diagonal and super diagonal, respectively. We can state the solvability of proposed scheme in the following theorem.

**Theorem 1.** The compact difference scheme (2.7) has a unique solution.

**Proof.** For any possible values of \( \mu_1, \mu_2 \) and \( h \) the coefficient matrix \( A \) is strictly diagonal dominant so it is nonsingular. Consequently the difference scheme (2.7) has a unique solution.
3. **STABILITY OF PROPOSED METHOD**

In the section we will analyze the stability of the finite difference scheme (2.7) by using the Fourier analysis. For \( x = (x_1, x_2, \ldots, x_{M-1})^T \in \mathbb{R}^{M-1} \), we define a discrete \( L^2 \)-norm by
\[
\|x^k\|_{L^2} = (h \sum_{j=1}^{M-1} x_j^2)^{1/2}.
\]
Let \( \tilde{U}_j^k \) be the approximate solution of (2.7) and define
\[
\rho_j^k = U_j^k - \tilde{U}_j^k, \quad k = 0, 1, \ldots, N, \quad j = 0, 1, \ldots, M,
\]
with corresponding vector
\[
\rho^k = (\rho_0^k, \rho_1^k, \ldots, \rho_{M-1}^k)^T.
\]

We obtain the following round off error equation
\[
\begin{align*}
(1 + \mu_2 + \left(\frac{1}{12} - \mu_1 + \frac{\mu_2}{12}\right) \delta_x^2) \rho_j^k &= \left(1 - \lambda_1 \mu_2 + \left(\frac{1}{12} + \lambda_1 \mu_1 - \frac{\lambda_1 \mu_2}{12}\right) \delta_x^2\right) \rho_j^{k-1} \\
+ \mu_1 \sum_{l=2}^{k} \lambda_l \delta_x^2 \rho_{j-l}^{k-l} - \mu_2 \sum_{l=2}^{k} \lambda_l \left(1 + \frac{1}{12} \delta_x^2\right) \rho_{j-l}^{k-l} + \tau \left(1 + \frac{1}{12} \delta_x^2\right) (f_j^{k-1} - \tilde{f}_j^{k-1}),
\end{align*}
\]
\[1 \leq j \leq M - 1, \quad 1 \leq k \leq N,
\]
with
\[
\rho_0^k = \rho_M^k = 0.
\]

in which \( \tilde{f}_j^{k-1} = f(\tilde{U}_j^{k-1}, x_j, t_{k-1}) \) We define the grid function
\[
\rho^k(x) = \begin{cases} 
\rho_j^k & \frac{h}{2} < x \leq x_j + \frac{h}{2} \\
0 & 0 \leq x < \frac{h}{2} \text{ or } L - \frac{h}{2} < x \leq L.
\end{cases}
\]

We can expand the \( \rho^k(x) \) in a Fourier series [5]
\[
\rho^k(x) = \sum_{l=-\infty}^{\infty} d_k(l) e^{i2\pi lx/L}, k = 1, 2, \ldots, N,
\]
where
\[ d_k(l) = \frac{1}{L} \int_0^L \rho^k(x) e^{i2\pi lx/L} \, dx. \]

Also we introduce the following norm
\[ \| \rho^k \|_2 = \left( \sum_{j=1}^{M-1} h | \rho^k_j |^2 \right)^{1/2} = \left[ \int_0^L | \rho^k(x) |^2 \, dx \right]^{1/2}. \]

By applying the Parseval equality
\[ \int_0^L | \rho^k(x) |^2 \, dx = \sum_{l=-\infty}^{\infty} | d_k(l) |^2, \]

we obtain
\[ \| \rho^k \|_2^2 = \sum_{l=-\infty}^{\infty} | d_k(l) |^2. \]  (3.2)

Now we can suppose that the solution of equation (3.1) has the following form

\[ \rho_j^k = d_k e^{i\sigma jh}, \]

where \( \sigma = \frac{2\pi l}{L} \). Substituting the above expression into (3.1) and putting \( \theta = \sigma h \), we obtain

\[ d_k = \frac{1}{\mu} \left[ \hat{\mu} + \sigma \sum_{l=2}^{k} \lambda_l d_{k-l} + \tau \left( 1 + \frac{1}{12} \delta^2 \right) \left( f_j^k - \tilde{f}_j^k \right) \right]. \]  (3.3)

where
\[
\mu = \frac{1}{3} \cos^2 \theta \frac{2}{2} + 4 \mu_1 \sin^2 \theta \frac{2}{2} + \frac{\mu_2}{3} \cos^2 \theta \frac{2}{2} + \frac{2}{3} \mu_2 + \frac{2}{3},
\]
\[
\hat{\mu} = \frac{1}{3} \cos^2 \theta \frac{2}{2} - 4 \lambda_\mu \sin^2 \theta \frac{2}{2} - \frac{\lambda_\mu \mu_2}{3} \cos^2 \theta \frac{2}{2} - \frac{2}{3} \lambda_\mu \mu_2 + \frac{2}{3}, \]
\[
\sigma = -4 \mu_1 \sin^2 \theta \frac{2}{2} - \frac{\mu_2}{3} \cos^2 \theta \frac{2}{2} - \frac{2}{3} \mu_2.
\]  (3.4)
Lemma 2. The coefficients $\lambda_i$ satisfy

\begin{align}
(1) \quad \lambda_0 &= 1, \quad \lambda_i = \gamma - 1, \quad \lambda_i < 0, \quad i = 1, 2, \ldots, \\
(2) \quad \sum_{i=0}^{n} \lambda_i &= 0, \quad -\sum_{i=1}^{n} \lambda_i < 1, \quad \forall n \in N.
\end{align}

Lemma 3. The coefficient $\mu$ in (3.4) satisfies $0 \leq \frac{1}{\mu} \leq 3$.

Proof. Since $\mu_1$ and $\mu_2$ are positive so from (3.4) we can write

$$1 \leq 3 \mu = \cos^2 \frac{\theta}{2} + 12 \mu \sin^2 \frac{\theta}{2} + \mu_1 \cos^2 \frac{\theta}{2} + 2 \mu_2 + 2,$$

which gives $0 \leq \frac{1}{\mu} \leq 3$.

Proposition 1. Suppose that $d_k (1 \leq k \leq N)$ are defined by (3.3), then we have

$$|d_k| \leq (1 + 3L\tau)^k |d_0|, \quad k = 1, 2, \ldots, N.$$

Proof. We will use mathematical induction to complete the proof. For $k = 1$, from (3.3) and using Lemma 3 we can write

$$|d_1| \leq \frac{1}{\mu} \left( \hat{\mu} |d_0| + \tau \left( 1 + \frac{1}{12} \delta_x^2 \right) e^{-ij\theta} |f_j^0 - \tilde{f}_j^0| \right)$$

$$\leq \frac{1}{\mu} \left( \hat{\mu} |d_0| + \tau \left( 1 + \frac{1}{12} \delta_x^2 \right) e^{-ij\theta} L |U_j^0 - \tilde{U}_j^0| \right)$$

$$\leq \frac{1}{\mu} \left( \hat{\mu} |d_0| + \tau \left( 1 + \frac{1}{12} \delta_x^2 \right) e^{-ij\theta} L |d_0| e^{ij\theta} \right)$$

$$= \left( \frac{\hat{\mu} + L\tau}{\mu} \right) |d_0| \leq (1 + 3L\tau) |d_0|.$$

Now suppose

$$|d_n| \leq (1 + 3L\tau)^n |d_0|, \quad n = 1, 2, \ldots, k - 1.$$
From (3.3) and induction hypothesis, we can write

\[
|d_k| \leq \frac{|d_0|}{\mu} (1 + 3L\tau)^{k-1} \left\{ \hat{\mu} + |\sigma| \sum_{l=0}^{k-2} |\lambda_{k,l-1}| \right\} + \frac{1}{\mu} \left\{ \tau \left( 1 + \frac{1}{12} \delta_x^2 \right) e^{-ij\theta} \right\} f_j^{k-1} - \tilde{f}_j^{k-1} \right) 
\]

\[
\leq \frac{|d_0|}{\mu} (1 + 3L\tau)^{k-1} \left\{ \hat{\mu} + |\sigma| \sum_{l=0}^{k-1} |\lambda_{k,l-1} - \lambda_{k,l_1}| \right\} + \frac{1}{\mu} \left\{ \tau \left( 1 + \frac{1}{12} \delta_x^2 \right) e^{-ij\theta} \right\} L |U_j^k - \tilde{U}_j^k| 
\]

\[
\leq \frac{|d_0|}{\mu} (1 + 3L\tau)^{k-1} \left\{ \hat{\mu} + |\sigma| \sum_{l=1}^{k} \left( -\lambda_{l} - |\lambda_{l_1}| \right) \right\} + \frac{1}{\mu} \left\{ \tau \left( 1 + \frac{1}{12} \delta_x^2 \right) e^{-ij\theta} \right\} L |d_{k-1}| e^{ij\theta} 
\]

\[
\leq \frac{|d_0|}{\mu} (1 + 3L\tau)^{k-1} \left\{ \hat{\mu} + |\sigma| \left( 1 - (1 - \gamma) \right) + L \right\} 
\]

\[
= (1 + 3L\tau)^k |d_0|,
\]

which completes the proof.

**Theorem 2.** The compact difference scheme (2.7) is unconditionally stable for any \( 0 < \gamma < 1 \).

**Proof.** Applying Proposition 1 and Parseval's equality, we obtain

\[
\|U_j^k - \tilde{U}_j^k\|_2^2 = \|\rho_j^k\|_2^2 = \sum_{j=1}^{M-1} |h\rho_j^k|_2^2 = h \sum_{j=1}^{M-1} |d_k^j e^{ij\hat{\theta}}|_2^2 = h \sum_{j=1}^{M-1} |d_k^j|_2^2 
\]

\[
\leq h \sum_{j=1}^{M-1} (1 + 3L\tau)^k |d_0|_2^2 \leq he^{3L\tau} \sum_{j=1}^{M-1} |d_0^j e^{ij\hat{\theta}}|_2^2 \leq e^{3L\tau} \|\rho_0\|_2^2 = e^{3L\tau} \|U_j^0 - \tilde{U}_j^0\|_2^2
\]

which means that the scheme (2.7) is unconditionally stable.

**4. CONVERGENCE OF PROPOSED METHOD**

In this section we prove that difference scheme (2.5) converges with the spatial accuracy of fourth order. We need some lemmas and theorems that will be expressed.
Lemma 4([2]). Regarding to the definitions of $\lambda_i$, we have

$$\tau^{\gamma-1} \sum_{l=0}^{k} \lambda_l = \frac{1}{\Gamma(\gamma)} + O(\tau).$$

On the basis (2.6) and Lemma 4, we have

$$R_j^k = O(\tau^2) \left(1 + \frac{1}{12} \delta_x^2 \right) + O(h^4) \sum_{l=0}^{k} \left( k_l \tau^{\gamma} \lambda_l \right)$$

$$= O(\tau^2) + \tau O(h^4) \kappa_l \tau^{\gamma-1} \sum_{l=0}^{k} \lambda_l$$

$$= O(\tau^2) + \tau O(h^4) \kappa_l \left( \frac{1}{\Gamma(\gamma)} + O(\tau) \right) = O(\tau^2 + \tau h^4),$$

so from (4.1), we can obtain

$$R_j^k = O(\tau^2 + \tau h^4),$$

$$k = 1, 2, \ldots, N, \quad j = 1, 2, \ldots, M,$$

therefore, there is a positive constant $C_1$, such that [3]

$$|R_j^k| \leq C_1 (\tau^2 + \tau h^4).$$

(4.2)

Similar to the stability analysis in Section 3, we define the grid functions [3]

$$e^k(x) = \begin{cases} 
 e_j^k & \text{when } \frac{h}{2} < x \leq x_j + \frac{h}{2}, \quad j = 1, 2, \ldots, M - 1, \\
 0 & \text{when } 0 \leq x \leq \frac{h}{2} \text{ or } L - \frac{h}{2} < x \leq L,
\end{cases}$$

and
\[
R^k(x) = \begin{cases} 
R_j^k & \text{when } x_j - \frac{h}{2} < x \leq x_j + \frac{h}{2}, \ j = 1,2,\ldots,M - 1, \\
0 & \text{when } 0 \leq x \leq \frac{h}{2} \ or \ L - \frac{h}{2} < x \leq L,
\end{cases}
\]

Thus \(e^k(x)\) and \(R^k(x)\) have the following Fourier series expansions

\[
e^k(x) = \sum_{l=-\infty}^{\infty} \eta_k(l)e^{\frac{i2\pi lx}{L}}, \quad k = 0,1,\ldots,N,
\]

\[
R^k(x) = \sum_{l=-\infty}^{\infty} \xi_k(l)e^{\frac{i2\pi lx}{L}}, \quad k = 0,1,\ldots,N,
\]

where

\[
\eta_k(l) = \frac{1}{L} \int_0^L e^k(x)e^{-\frac{i2\pi lx}{L}} \, dx, \quad k = 0,1,\ldots,N,
\]

\[
\xi_k(l) = \frac{1}{L} \int_0^L R^k(x)e^{-\frac{i2\pi lx}{L}} \, dx, \quad k = 0,1,\ldots,N.
\]

Now, we define the following notations [3]

\[
e_j^k = u(x_j, t_k) - U_j^k = \bar{u}_j^k - U_j^k, \quad k = 1,2,\ldots,N, \quad j = 1,2,\ldots,M,
\]

\[
e^k = [e_1^k, e_2^k, \ldots, e_{M-1}^k], \quad R^k = [R_1^k, R_2^k, \ldots, R_{M-1}^k], \quad k = 1,2,\ldots,N,
\]

and introduce the following norms

\[
\|e\|_2 = \left( \sum_{j=1}^{M-1} h |e_j^k|^2 \right)^{\frac{1}{2}} = \left[ \int_0^L |e^k(x)|^2 \, dx \right]^{\frac{1}{2}}, \quad k = 0,1,\ldots,N,
\]
Numerical solution of a fractional PDE in the electroanalytical chemistry

\[ \| R \|_2 = \left( \sum_{j=1}^{M-1} h |R_j^k|^2 \right)^{\frac{1}{2}} = \left[ \int_0^L |R^k(x)|^2 \, dx \right]^{\frac{1}{2}}, \quad k = 0, 1, \ldots, N. \]  

(4.5)

Using the Parseval equality

\[ \int_0^L |e^k(x)|^2 \, dx = \sum_{l=-\infty}^{\infty} |\eta_k(l)|^2, \quad k = 0, 1, \ldots, N, \]

and

\[ \int_0^L |R^k(x)|^2 \, dx = \sum_{l=-\infty}^{\infty} |\xi_k(l)|^2, \quad k = 0, 1, \ldots, N, \]

we also have

\[ \| e^k \|_2^2 = \sum_{l=-\infty}^{\infty} |\eta_k(l)|^2, \quad k = 0, 1, \ldots, N, \]  

(4.6)

\[ \| R^k \|_2^2 = \sum_{l=-\infty}^{\infty} |\xi_k(l)|^2, \quad k = 0, 1, \ldots, N. \]  

(4.7)

From (2.6), we obtain that

\[
\begin{align*}
\left(1 + \frac{1}{12} \delta_x^2 \right) \bar{u}_j^k &= \left(1 + \frac{1}{12} \delta_x^2 \right) \bar{u}_j^{k-1} + \mu_k \sum_{l=0}^{k-1} \lambda_l \xi_{j-l} \bar{u}_j^{k-l} \\
+ \mu_k \sum_{l=0}^{k-1} \lambda_l \left(1 + \frac{1}{12} \delta_x^2 \right) \bar{u}_j^{k-l} + \tau \left(1 + \frac{1}{12} \delta_x^2 \right) f_j^{k-1} + R_j^k
\end{align*}
\]

(4.8)

\[ k = 1, 2, \ldots, N, \quad j = 1, 2, \ldots, M, \]

where \( \bar{u}_j^k = u(x_j, t_k) \) and \( f_j^{k-1} = f(\bar{u}_{j-1}^{k-1}, x_j, t_{k-1}) \). Subtracting (2.7) from (4.8), leads to
\[ \left\{ \begin{array}{l} \left( 1 + \frac{1}{12} \delta_x^2 \right) e_j^0 = \left( 1 + \frac{1}{12} \delta_x^2 \right) e_j^{k-1} + \mu \sum_{l=0}^{k} \lambda_l \delta_x^2 e_j^{k-l} \\
+ \mu \sum_{l=0}^{k} \lambda_l \left( 1 + \frac{1}{12} \delta_x^2 \right) e_j^{k-l} + \tau \left( 1 + \frac{1}{12} \delta_x^2 \right) f_j^{k-1} + R_j^k \end{array} \right. \] (4.9)
\[
e_j^k = e_j^k = 0, \quad e_j^0 = 0, \quad k = 1, 2, \ldots, N, \quad j = 1, 2, \ldots, M.
\]

Now we assume that \( e_j^k \) and \( R_j^k \) are
\[
e_j^k = \eta_k e^{i(\sigma jh)},
\]
\[
R_j^k = \xi_k e^{i(\sigma jh)},
\]
where \( \sigma = \frac{2l \pi}{L} \). Substituting the above relations into (4.9) results
\[
\eta_k = \frac{1}{\mu} \left[ \hat{\mu} + \omega \sum_{l=2}^{k} \hat{\lambda}_l \eta_{k-l} + \tau \left( 1 + \frac{1}{12} \delta_x^2 \right) e^{-i\theta} \left( f_j^k - f_j^{k-1} \right) + \xi_k \right],
\]
(4.10)

\[
k = 1, 2, \ldots, N.
\]

Notice that \( e^0 = 0 \) and we have
\[
\eta_0 \equiv \eta_0(l) = 0.
\]

In addition, from the left hand equality of (4.5) and (4.2), we obtain [3]
\[
\left\| R_j^k \right\|_2 \leq \sqrt{MhC_1 \left( \tau^2 + \tau h^4 \right)} = C_1 \sqrt{L} \left( \tau^2 + \tau h^4 \right). \] (4.11)

Also from convergence of the series in the right hand side of (4.7), there is a positive constant \( C_2 \) such that [3]
\[
\left| \xi_k \right| \leq \left| \xi_k (n) \right| \leq C_2 L \tau \left| \xi_1 \right| = C_2 L \tau \left| \xi_1 (n) \right|, \quad k = 1, 2, \ldots, N. \] (4.12)

\textbf{Proposition 2.} If \( \eta_k \) \( (k = 1, 2, \ldots, N) \) be the solutions of equation (4.10), then there is a positive constant \( C_2 \) such that
\[
\left| \eta_k \right| \leq C_2 k \left( 1 + 3L \tau \right)^k \left| \xi_1 \right|, \quad k = 1, 2, \ldots, N.
\]
Proof. We use the mathematical induction for proof. Firstly, from (4.10) and (4.12) we have

\[ |\eta_1| \leq \frac{1}{\mu} |\xi_1| \leq \tau C_2 L |\xi_1| \leq 3C_2 L \tau |\xi_1| \leq 3C_2 L \tau |\xi_1| \leq C_2 (1 + 3L \tau) |\xi_1|. \]

Now, suppose that

\[ |\eta_n| \leq C_2 n (1 + 3L \tau)^n |\xi_1|, \quad n=1,2,...,k-1 \]

From Lemma 2 and noticing that \( \hat{\mu} > 0 \) we have,

\[ |\eta_k| \leq \frac{C_2 (k-1)}{\mu} (1 + 3L \tau)^{k-1} \left\{ \hat{\mu} + |\sigma| \left( \sum_{l=0}^{k-2} |\lambda_{k-l}| \right) |\xi_1| \right. \\
\left. + \frac{1}{\mu} \left\{ \tau e^{-ij\theta \frac{1}{12} \delta_x^2} \left[ f_j^k - \tilde{f}_j^k \right] \right\} + \tau C_2 L |\xi_1| \right\} \\
\leq \frac{C_2 (k-1)}{\mu} (1 + 3L \tau)^{k-1} \left\{ \hat{\mu} + |\sigma| \left( \sum_{l=0}^{k-2} |\lambda_{k-l}| \right) + \tau L \right\} |\xi_1| + 3C_2 \tau L |\xi_1| \\
\leq \frac{C_2 (k-1)}{\mu} (1 + 3L \tau)^{k-1} \left\{ \hat{\mu} + |\sigma| \left( \sum_{l=1}^{k} |\lambda_l| \right) + \tau L \right\} |\xi_1| + (1 + 3L \tau)^{k} C_2 |\xi_1| \\
\leq \frac{C_2 (k-1)}{\mu} (1 + 3L \tau)^{k-1} \left\{ \hat{\mu} + |\sigma| \right\} |\gamma + \tau L |\xi_1| + (1 + 3L \tau)^{k} C_2 |\xi_1| \\
\leq C_2 (k-1) (1 + 3L \tau)^{k-1} \left( \frac{\hat{\mu} + \tau L}{\mu} \right) |\xi_1| + (1 + 3L \tau)^{k} C_2 |\xi_1| \\
= k C_2 (1 + 3L \tau)^{k} |\xi_1|. \]

Theorem 3. Suppose \( u(x,t) \) is the exact solution of the Eq. (1.6), then the compact finite difference scheme (2.7) is \( L_2 \)-convergent with convergence order \( O(\tau + h^4) \).

Proof. By considering Proposition 2 and noticing (4.6), (4.7) and (4.11), we can obtain

\[ \| e^k \|_2 \leq C_2 k (1 + 3L \tau)^k \| R^1 \|_2 \leq C_1 \tau \sqrt{L} C_2 k e^{3kL \tau} (\tau + h^4). \]
Since \( k \tau \leq T \), we have
\[
\| e^k \|_2 \leq C(\tau + h^4)
\]
in which
\[
C = C_1 C_2 T \sqrt{\lambda} e^{3T^\lambda},
\]
and this completes the proof.

5. Numerical Results

In this section we present the numerical results of the new method on several test problems. We tested the accuracy and stability of the method described in this paper by performing the mentioned scheme for different values of \( h \) and \( \tau \). We performed our computations using Matlab 7 software on a Pentium IV, 2800 MHz CPU machine with 2 Gbyte of memory. We calculated the computational orders of the method presented in this article in time variable with [17, 24]
\[
C_1 \text{-order} = \log_2 \left( \frac{\| L_\alpha(2\tau, h) \|}{\| L_\alpha(\tau, h) \|} \right),
\]
and in space variables with [4]
\[
C_2 \text{-order} = \log_2 \left( \frac{\| L_\alpha(16\tau, 2h) \|}{\| L_\alpha(\tau, h) \|} \right).
\]

5.1 Test problem 1.

We consider the fractional linear PDE
\[
\frac{\partial u(x, t)}{\partial t} = 0 D_t^{1-\gamma} \left[ \frac{\partial^2 u(x, t)}{\partial x^2} - u(x, t) \right] + (1 + \gamma)e^{x} t^{\gamma}, \tag{5.1}
\]
with boundary and initial conditions
\[ u_0^k = t^{1+\gamma}, \quad u_M^k = e^{L t^{1+\gamma}}, \quad k = 1, 2, \ldots, N, \]

\[ u_j^0 = 0, \quad j = 1, 2, \ldots, M. \]  

(5.2)

Then, the exact solution of (5.1), (5.2) is

\[ u(x,t) = e^{x t^{1+\gamma}}. \]

We solve this problem with the method presented in this article with several values of \( h \), \( \tau \) and \( \gamma \) for \( L = 1 \) at final time \( T = 1 \). The \( L_\infty \), \( C_1 \)-order, \( C_2 \)-order and CPU time (s) of applied method are shown in Tables 1,2.

**Table 1.** Errors and computational orders obtained for test problem 1 with \( h = \frac{1}{20} \).

</tbody>
</table>

5.2 Test problem 2.

We consider the fractional PDE with the nonlinear source term

\[
\frac{\partial u(x,t)}{\partial t} = D_t^{1-\gamma} \left[ \frac{\partial^2 u(x,t)}{\partial x^2} - u(x,t) \right] + u^3(x,t) + \cos(\pi x) \left[ 2t + (\pi^2 + 1) \frac{2^{1+\gamma}}{\Gamma(2+\gamma)} t^6 \cos^2(\pi x) \right],
\]

with boundary and initial conditions

\[ u^k_0 = t^2, \quad u^k_M = t^2 \cos(\pi L), \quad k = 1,2,\ldots,N, \]

\[ u^0_j = 0, \quad j = 1,2,\ldots,M. \]

where, the exact solution is

\[ u(x,t) = t^2 \cos(\pi x). \]
We solve this problem with the method presented in this article with several values of \( h, \tau \) and \( \gamma \) for \( L = 1 \) at final time \( T = 1 \). The \( L_\infty \) error, \( C_1 \)-order, \( C_2 \)-order and CPU time (s) of applied method are shown in Tables 3, 4.

**Table 3.** Errors and computational orders obtained for test problem 2 with \( h = \frac{1}{16} \)

\[
\begin{array}{cccccc}
\tau & L_\infty & C_1 \text{- order} & L_\infty & C_1 \text{- order} & \text{CPU time(s)} \\
\hline
1/10 & 3.3534 \times 10^{-2} & \_ & 3.9372 \times 10^{-2} & \_ & 0.1250 \\
1/20 & 1.7050 \times 10^{-2} & 0.9758 & 2.0125 \times 10^{-2} & 0.9682 & 0.1879 \\

6. CONCLUSION

In this article, we constructed a compact difference scheme for the solution of a fractional nonlinear PDE in the electroanalytical chemistry. This compact difference scheme has the advantage of high accuracy and unconditional stability which we proved it using the Fourier analysis. Also we show that the proposed compact finite difference scheme converges with the spatial accuracy of fourth-order. Numerical results confirmed the theoretical results of proposed method.

REFERENCES
